

Project Explanation (200–300 Words)

This project demonstrates an AI-powered Travel Assistant built using n8n and the Model Context Protocol (MCP). The primary objective was to provide accurate and real-time travel recommendations by allowing the AI Agent to access external tools instead of relying only on the language model's internal knowledge. The workflow begins with a Chat Trigger that accepts a user's travel request. The request is then processed by an AI Agent connected to a Groq language model, Simple Memory, and an MCP Client. Through the MCP Client, the agent retrieves live information such as destination coordinates, current weather, hotels, restaurants, tourist attractions, and currency exchange rates for international trips. After collecting all tool responses, the AI Agent combines the information into a clear and personalized travel itinerary. Simple Memory is included to remember user preferences such as budget, hotel type, transportation method, food preferences, and preferred activities, enabling more personalized recommendations in future conversations. MCP significantly improves the quality of the workflow because it provides up-to-date information from external services rather than static model knowledge. During development, challenges included configuring the MCP connection, ensuring all tools were available, and handling temporary model service interruptions. These issues were resolved by validating the MCP endpoint, testing each tool individually, and using a stable Groq model. The final workflow successfully delivers intelligent, accurate, and user-focused travel planning.
